

Welcome

Summer School Digital Tools for Humanists

Pisa – June 7-16 2022

Refresher

Refresher on Computer Fundamentals and Networking

History of computers

- Architecture of a computer

- Data representation within a computer
- Computer networks and the Internet
- The Semantic Web

Early visions

Charles Babbage 1791-1871

Professor of Mathematics, Cambridge University, 1827-1839

Babbage's engines

- Difference Engine 1823
- Analytic Engine 1833
 - The forerunner of modern digital computer

Technology

 mechanical gears, Jacquard's loom (1801), simple calculators

Programming

Ada Lovelace

Application

- Mathematical Tables Astronomy
- Nautical Tables Navy

Use of punched paper tape

The organ grinder

Early experiments 100 years later

- Z1 machine (Konrad Zuse, , private entrepreneur, 1936-1941)
- ABC (Atanasoff-Berry Computer, Iowa State University, 1937-1942)
- Mark I (Howard Aiken, MIT, 1937-1941)

1942 Second World War

Harvard Mark I

- Built in 1944 in IBM Endicott laboratories
 - Howard Aiken Professor of Physics at Harvard
 - Essentially mechanical but had some electro-magnetically controlled relays and gears
 - Weighed 5 tons and had 750,000 components
 - A synchronizing clock that beat every 0.015 seconds (66KHz)

Performance:

- 0.3 seconds for addition
- 6 seconds for multiplication
- 1 minute for a sine calculation

WW-2 Fffort

Broke down once a week!

ENIAC

- Inspired by Atanasoff and Berry, Eckert and Mauchly designed and built ENIAC (1943-45) at the University of Pennsylvania
- The first, completely electronic, operational, general-purpose analytical calculator!
 - 30 tons, 72 square meters, 200KW
- Performance
 - Read in 120 cards per minute
 - Addition took 200 μs, Division 6 ms
 - 1000 times faster than Mark I
- Not very reliable!

Application: Ballistic calculations

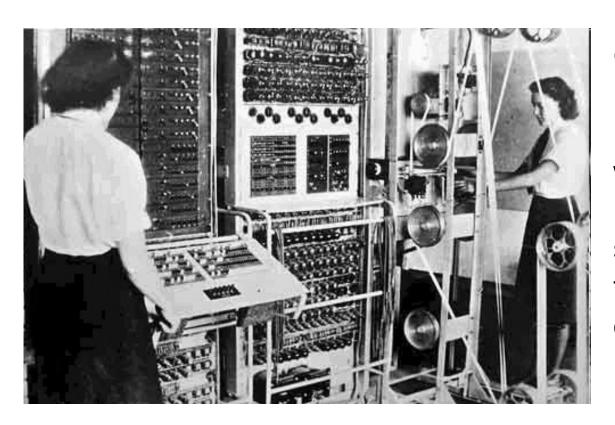

WW-2 Fffort

Colossus

Colossus (derived in 1943 from Mark1 and Mark2) was used in London during the second World War to decipher encrypted German messages (Enigma machine)

EDVAC - Electronic Discrete Variable Automatic Computer

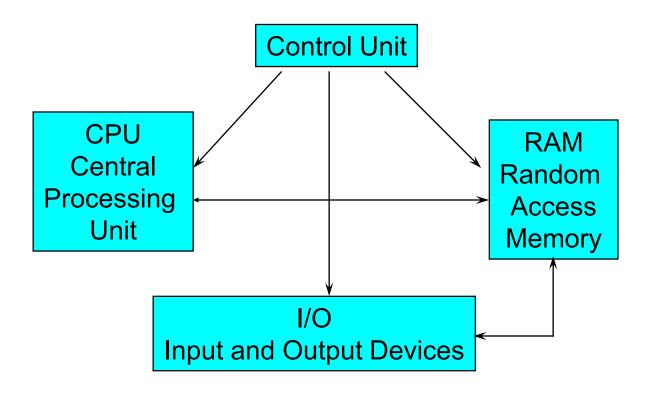

- ENIAC's programming system was external
 - Sequences of instructions were executed independently of the results of the calculation
 - Human intervention required to take instructions "out of order"
- Eckert, Mauchly, John von Neumann and others designed EDVAC (1944-1945) to solve this problem
 - Solution was the stored program computer
 - ⇒ "program can be manipulated as data"
- First Draft of a report on EDVAC was published in 1945, but just had von Neumann's signature
- In 1973 the court of Minneapolis attributed the honor of inventing the computer to John Atanasoff

Von Neuman architecture

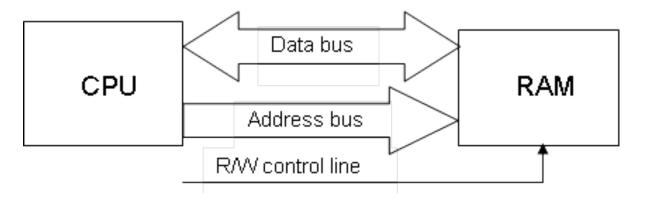

Random Access Memory

- The RAM is a linear array of "cells", usually called "words". The words are numbered from 0 to N, and this number is the "address" of the word
- In order to read/write a word from/into a memory cell, the CPU has to provide its address on the "address bus"
- A "control line" tells the memory whether it is a read or write operation
- In a read operation the memory will provide on the "data bus" the content of the memory cell at the address provided on the "address bus"
- In a write operation the memory will store the data provided on the "data bus" into the memory cell at the address provided on the "address bus", overwriting previous content

Program execution

- The RAM contains both the program (machine instructions) and the data
- The basic model is "sequential execution"
 - each instruction is extracted from memory (in sequence) and executed
- Basic execution cycle
 - Fetch instruction (from memory) at location indicated by LC
 - Increment Location Counter (to point to the next instruction)
 - Bring instruction to CPU
 - Execute instruction
 - Fetch operand from memory (if needed)
 - Execute operation
 - Store result
 - in "registers" (temporary memory)
 - in memory (RAM)

Data within a computer

- The Control Unit, the RAM, the CPU and all the physical components in a computer act on electrical signals and on devices that (basically) can be in only one of two possible states
- The two states are conventionally indicated as "zero" and "one" (0 and 1), and usually correspond to two voltage levels
- The consequence is that all the data within a computer (or in order to be processed by a computer) has to be represented in binary notation, i.e. with a sequence of 0s and 1s, called bits

Evolution of computer technology

- First Generation mechanical/electromechanical
- Second Generation vacuum tubes
- Third Generation discrete transistors (solid state devices) SSI, MSI, LSI integrated circuits
- Fourth Generation
 VLSI integrated circuits

VLSI = Very Large Scale Integration

Evolution of computer components

- Computer technology
 - CPU on integrated chips
 - From KHz to MHz to GHz
 - Random Access Memories
 - RAM from KB to GB
 - External memories
 - Tapes, hard disks, floppy disks
 - Memory sticks
 - CDs
 - DVDs
 - from MB to GB to TB to PB to EB

Size of digital information

1000	k	kilo
1000 ²	М	mega
1000 ³	G	giga
1000 ⁴	T	tera
1000 ⁵	Р	peta
1000 ⁶	Е	exa
1000 ⁷	Z	zetta
10008	Υ	yotta

Evolution of the software

- Operating systems
 - Multi user
 - Multi tasking (e.g. Windows)
- Applications
 - Client-Server (e.g. the Web)
 - Multimedia
- Communication (networking)

Evolution of computer market

- Military applications in early 40s
- Scientific/research applications in late 40s
- Commercial applications appear in early 50s
- Monopoly of IBM starts with 650, 701, 702
- Monopoly of IBM continues with 7070, 7090 and the 360 series, starting the "mainframe era" (in the 60s)
- Arrival of the "minicomputers" in the 70s
- Arrival of the PC in the 80s
- Arrival of the Internet in the 90s
- Arrival of the Web in the 90s

Harvard Mark I, 1943

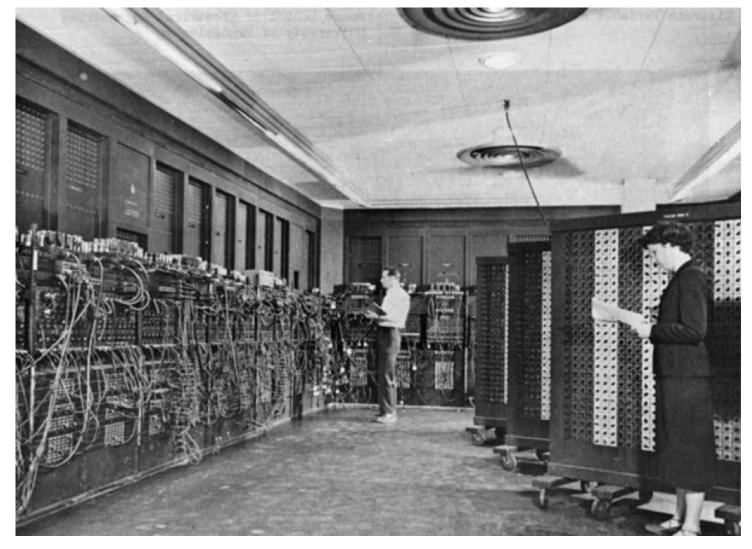

ENIAC - Electronic Numerical Integrator And Computer

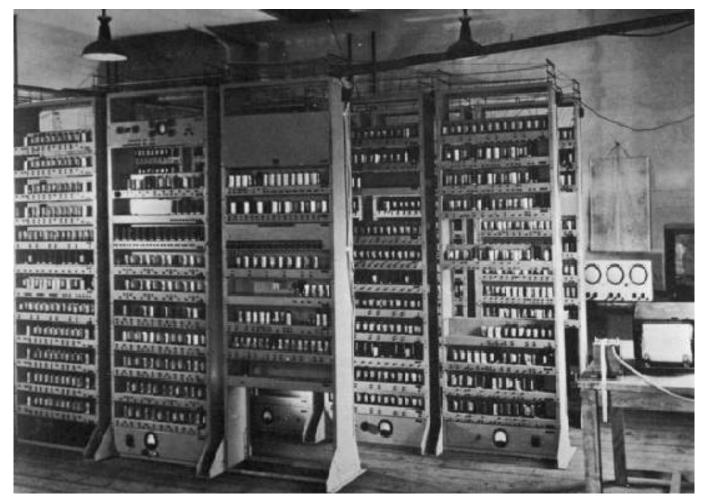

EDSAC - Electronic Delay Storage Automatic Calculator

EDSAC, University of Cambridge, UK, 1949

A "mainframe" in the 60'

A "mainframe" in the 70'

Minicomputers

Early PCs

Refresher

Refresher on Computer Fundamentals and Networking

- History of computers
- Architecture of a computer
- Data representation within a computer

- Computer networks and the Internet
- The Semantic Web

Data within a computer

- The Control Unit, the RAM, the CPU and all the physical components in a computer act on electrical signals and on devices that (basically) can be in only one of two possible states
- The two states are conventionally indicated as "zero" and "one" (0 and 1), and usually correspond to two voltage levels
- The consequence is that all the data within a computer (or in order to be processed by a computer) has to be represented in binary notation, i.e. with a sequence of 0s and 1s, called bits

Representation of information within a computer

- Numbers
- Text (characters and ideograms)
- Documents
- Images
- Video
- Audio

Positional notation in base 10

Ten different symbols are needed for the digits (0,1,2,3,4,5,6,7,8,9)

The "weight" of each digit is a power of 10 (the base) and depends on its position in the number

$$10^{0}=1$$
 $10^{1}=10$
 $10^{2}=100$
 3
 4
 7
 $10^{3}=1000$
 $3x10^{2} + 4x10^{1} + 7x10^{0} = 347$
 $10^{4}=10000$

Positional notation in base 8

Eight different symbols are needed for the digits (0,1,2,3,4,5,6,7)

The "weight" of each digit is a power of 8 (the base) and depends on its position in the number

$$8^{0}=1$$
 $8^{1}=8$
 $8^{2}=64$
 $8^{3}=512$

 $8^4 = 4096$

Positional notation in base 16

Sixteen different symbols are needed for the digits (0,1,2,3,4,5,6,7, 8,9,A,B,C,D,E,F)

The "weight" of each digit is a power of 16 (the base) and depends on its position in the number

$$16^{0}=1$$

$$16^{1}=16$$

$$16^2 = 256$$

$$16^3 = 4096$$

$$16^4 = 65536$$

$$3x16^2 + Bx16^1 + Fx16^0$$

$$3x256 + 11x16 + 15x1$$

Positional notation in base 2

Two different symbols are needed for the digits (0,1)

The "weight" of each digit is a power of 2 (the base) and depends on its position in the number

$$2^{0}=1$$

$$2^{1}=2$$

$$2^2 = 4$$

$$2^3 = 8$$

$$2^{4}=16$$

$$2^{5}=32$$

$$2^6 = 64$$

$$2^{7}=128$$

$$2^{8}=256$$

$$1x2^3 + 0x2^2 + 1x2^1 + 1x2^0$$

$$1x8 + 0x4 + 1x2 + 1x1$$

$$8 + 0 + 2 + 1 = 1$$

Powers of 2

20=1	2 ⁹ =512		
21=2	2 ¹⁰ =1024	1K	
2 ² =4	$2^{11}=2048$	2K	
2 ³ =8	2^{12} =4096	4K	
2 ⁴ =16	2 ¹³ =8192	8K	
2 ⁵ =32	2 ¹⁴ =16384	16K	
2 ⁶ =64	2^{15} =32768	32K	
2 ⁷ =128	2 ¹⁶ =65356	64K	
2 ⁸ =256			
	2 ²⁰ =1.048.57	2 ²⁰ =1.048.576	
	2 ³⁰ =1.073.741.824		1024M

232=4.271.406.736

1M

1G

4G

4096M

Binary and hexadecimal numbers

2°=1	0 0 0 0 = 0	1000=8	
21=2	001=1	1001=9	
$2^2 = 4$	0010=2	1010=10	A
$2^3 = 8$	0011=3	1011=11	В
24=16	0100=4	1100=12	C
25=32	0101=5	1101=13	D
$2^6 = 64$	0110=6	1110=14	E
2 ⁷ =128	0111=7	1111=15	F
$2^8 = 256$	l	10000=16	10

decimal and exadecimal

decimal hexadecimal

0101 1011 can be represented in hexadecimal as 5B

Representation of information within a computer

- Numbers
- Text (characters and ideograms)

- Documents
- Images
- Video
- Audio

Representation of characters

- The most simple way to represent (alphanumeric) characters (and symbols) within a computer is to associate a character (a symbol) with a number, defining a "coding table"
- How many bits are needed to represent the Latin alphabet?

The ASCII table (7 bits)

```
0123456789:;<=>?
@ABCDEFGHIJKLMNO
PQRSTUVWXYZ[\]^
`abcdefghijklmno
pqrstuvwxyz{|}~
```

The 95
printable
ASCII
characters,
numbered
from 32 to
126 (decimal)

33 control characters

ASCII table (7 bits)

Dec	Hex	Char	Dec	Нех	Char	Dec	Hex	Char	Dec	Hex	Char

First 3 bits

Representation standards

- ASCII 7 bits (late fifties)
 - American Standard Code for Information Interchange
 - 7 bits for 128 characters (Latin alphabet, numbers, punctuation, control characters)
- EBCDIC (early sixties)
 - Extended Binary Code Decimal Interchange Code
 - 8 bits; defined by IBM in early sixties, still used and supported on many computers
- ASCII 8 bits (ISO 8859-xx) extends original ASCII to 8 bits to include accented letters and non Latin alphabets (e.g. Greek, Russian)
- UNICODE or ISO-10646 (1993)
 - Merged efforts of the Unicode Consortium and ISO
 - UNIversal CODE still evolving
 - It incorporates all(?) the pre-existing representation standards
 - Basic rule: round trip compatibility
 - Side effect is multiple representations for the same character

ISO-8859-xx (ASCII 8-bits)

- Developed by ISO (International Organization for Standardization)
- There are 16 different tables coding characters with 8 bit
- Each table includes ASCII (7 bits) in the lower part and other characters in the upper part for a total of 191 characters and 32 control codes
- It is also known as ISO-Latin—xx (includes all the characters of the "Latin alphabet")

ISO-8859-xx code pages

8859-1	Latin-1	Western European	languages
0000 .		manage and a second	

8859-2 Latin-2 Central European languages

8859-3 Latin-3 South European languages

8859-4 Latin-4
 North European languages

8859-5 Latin/Cyrillic Slavic languages

8859-6 Latin/Arabic Arabic language

8859-7 Latin/Greek modern Greek alphabet

8859-8 Latin/Hebrew modern Hebrew alphabet

8859-9 Latin-5 Turkish language (similar to 8859-1)

8859-10 Latin-6
 Nordic languages (rearrangement of Latin-4)

8859-11 Latin/Thai
 Thai language

8859-12 Latin/Devanagari Devanagari language (abandoned in 1997)

8859-13 Latin-7 Baltic Rim languages

8859-14 Latin-8 Celtic languages

8859-15 Latin-9 Revision of 8859-1

8859-16 Latin-10
 South-Eastern European languages

Representation standards

- ASCII (late fifties)
 - American Standard Code for Information Interchange
 - 7 bits for 128 characters (Latin alphabet, numbers, punctuation, control characters)
- EBCDIC (early sixties)
 - Extended Binary Code Decimal Interchange Code
 - 8 bits; defined by IBM in early sixties, still used and supported on many computers
- ISO 8859-1 extends ASCII to 8 bits (accented letters, non Latin characters)
- UNICODE or ISO-10646 (1993)
 - Merged efforts of the Unicode Consortium and ISO
 - UNIversal CODE still evolving
 - It incorporates all(?) the pre-existing representation standards
 - Basic rule: round trip compatibility
 - Side effect is multiple representations for the same character

UNICODE

- In Unicode, the word "character" refers to the notion of the abstract form of a "letter", in a very broad sense
 - a letter of an alphabet
 - a mark on a page
 - a symbol (in a language)
- A "glyph" is a particular rendition of a character (or composite character). The same Unicode character can be rendered by many glyphs
 - Character "a" in 12-point Helvetica, or
 - Character "a" in 16-point Times
- In Unicode each "character" has a name and a numeric value (called "code point"), indicated by U+hex value.
 For example, the letter "G" has:
 - Unicode name: "LATIN CAPITAL LETTER G"
 - Unicode value: U+0047 (see ASCII codes)

Unicode representation

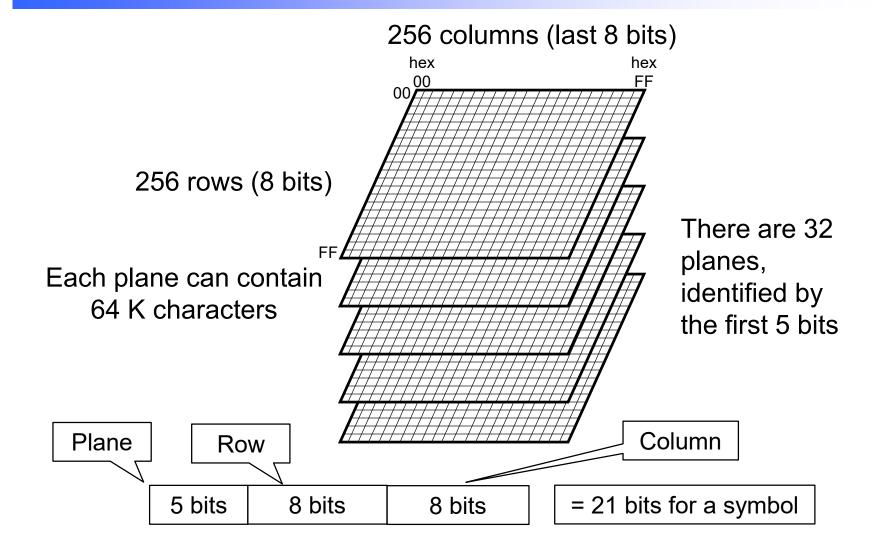

- The Unicode standard has specified (and assigned values to) about 96.000 characters
- Representing Unicode characters (code points) in binary
 - 32 bits in ISO-10646
 - 21 bits in the Unicode Consortium
- In the 21 bit address space, we can take the last 16 bits to address a "plane" of 64K characters (256 rows by 256 columns)
- The first five bits can then identify one of the 32 possible planes
- Only 6 planes defined as of today, of which only 4 are actually "filled"
- Plane 0, the Basic Multingual Plane, contains most of the characters used (as of today) by most of the languages present in the Web

The planes of Unicode

Beginning of BMP

in this table each "column" represents 16 characters

	0	1	2	3	4	5	6	7	8	9	АВ	C D E F					
00	C0 Co	ntrols			Basic	c Latin	C1 Controls <u>Latin 1 Supplement</u>

0 E	<u>Thai</u>									<u>Lao</u>							
0F								Tibetar									
10					Mya	<u>nmar</u>			<u>Georgian</u>								

Unicode encoding

- UTF-32 (fixed length, four bytes)
 - UTF stands for "UCS Transformation Format" (UCS stands for "Unicode Character Set")
 - UTF-32BE and UTF-32LE have a "byte order mark" to indicate "endianness"
- UTF-16 (variable length, two bytes or four bytes)
 - All characters in the BMP represented by two bytes
 - The 21 bits of the characters outside of the BMP are divided in two parts of 11 and 10 bits; to each part is added an offset to bring it in the "surrogate zone" of the BMP (low surrogate at D800 and high surrogate at DC800)
 - in other words, they are represented as two characters in the BMP
 - UTF-16BE and UTF-16LE to indicate "endianness"
- UTF-8 (variable length, 1 to 4 bytes)
 - Characters in the 7-bit ASCII represented by one byte
 - Variable length encoding (2, 3 or 4 bytes) for all other characters

UTF-8

Table 4.3 Encoding the Unicode character set as UTF-8.

Unicode value	21-bit binary code	UTF-8 code							
U + 00000000 - U + 0000007F	0000000000000wwwwwwwww	0wwwwww							
U + 00000080 - U + 000007FF	000000000wwwwxxxxxx	110wwwww 10xxxxx	x

Representation of information within a computer

- Numbers
- Text (characters and ideograms)
- Documents

- Images
- Video
- Audio

Representing documents

- Plain text
 - No information about structure
 - Different representation for line breaks

Knowledge of internal representation needed to extract text

- Windows represent a new line with the sequence "carriage return" followed by "line feed"
- Unix and Apple/Mac represent a new line with "line feed" only
- Page description languages
 - PostScript
 - PDF Portable Document Format
- Word processors (text editors)
 - RTF Rich Text Format
 - Microsoft Word
 - LaTeX

Text editors

Editing of the contents

Editing of the format

- Mark-up languages
- WYSIWYG (What You See Is What You Get)

PostScript

- First commercially available page description language (Adobe 1985)
- It is a real programming language (variables, procedures, etc.) and a PostScript document is actually a "PostScript program"
- A page description comprises a number of graphical drawing instructions, including those that draw letters in a specific font in a specific size
 - Type-1 (Adobe) fonts versus TrueType (Apple)
- The document can be printed (or displayed) by having a "PostScript interpreter" executing the program
- The "abstract" PostScript description is converted to a matrix of dots ("rasterization" or "rendering")
- PostScript initially designed for printing
 - Photo typesetters resolution up to 12000 dpi (dots per inch)
- PostScripts documents in a Digital Library
 - Extraction of text not always immediate
 - Digital Library must have a PostScript interpreter

PDF Portable Document Format

- Successor to PostScript, to include good support for displays
- No longer a real programming language
- It defines an overall structure for a pdf document
 - Header, objects, cross-references, trailer
- Support for interactive display
 - Hierarchically structured content
 - Random access to pages
 - Navigation within a document
 - Support of hyperlinks
 - Support of "searchable images"
 - Limited editing capabilities
 - pdf/A "standard" format for "archiving"

ODF – Open Document Format

- .odt a text document
- .ods a spreadsheet file
- .odp a presentation file
- .odg an illustration or graphic

Internal format is a zip-compressed XML document Versions of the OpenDocument Format are available for free download and use

LaTeX

- Widely used in the scientific and mathematical communities
- Based on TeX, defined in the late seventies by Don Knuth, to overcome the limitations of the typesetters available at the time
- LaTeX documents are expressed in plain text, to expose all the details of the internal representation
 - Any text editor on any platform can be used to compose LaTeX document
 - Converted to a page description language (typically PostScript or PDF) to get the formatted document
- Simple document structure
 - Preamble to set the defaults and the global features
 - Structured (sections and subsections) document content
- Highly customizable with "external packages"
- Text extraction not so immediate
 - A single document may occupy several files
 - Possibility of "too much" customization

Proprietary format Word (.doc, .docx)

- Last published specification is that of Word 97
 - Many changes since then
- Internal binary format (more fast and more compact with respect to the other formats)
- Abstract document structure similar to rtf documents
- More rich in functionality, and therefore more complicated
- The "Fast Save" option does not preserve the order of the text
 - Edits are appended at the end of the document
- For text extraction the best alternative is to save in some open format, such as odt, rtf, html

Representation of information within a computer

- Numbers
- Text (characters and ideograms)
- Documents
- Images

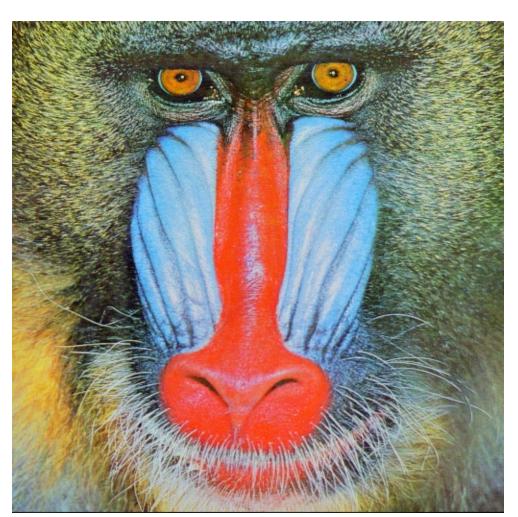

- Video
- Audio

Welcome

Welcome to image representation and compression

Representation of images

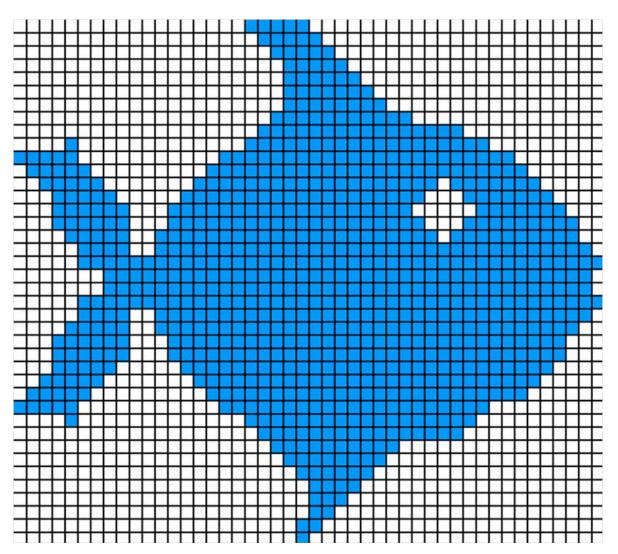

- Vector formats (geometric description)
 - Main advantage is scalability
 - Postscript
 - PDF
 - SVG (Scalable Vector Graphics)
 - SWF (ShockWave Flash)
 - vector-based images, plus audio, video and interactivity
 - Flash player obsolete since end of 2020
- Raster formats (array of "picture elements", called "pixels")

Picture elements (pixels)

A pixel must be small enough so that its color can be considered uniform for the whole pixel. Inside the computer, a pixel is represented with a number representing its color.

UNIPI SUMMER SCHOOL 2022

Raster format

- In raster format an image (picture) is represented by a matrix of "pixels"
- A first measure of the quality of a picture is given by the number of pixels, which can be measured in different ways
- Total number of pixels, as in digital cameras and phones
 - from 3-5 MegaPixels to 30-50 MegaPixels
- Number of rows and columns of the matrix, like in TV or PC screens (columns by rows)
 - HDTV 1920x1080, 4K TV 3840 x 2160,
 - PC screen 1024x768, 1280x1024, 1920x1080
- Number of pixels in 1 inch (2,54 cm), called "dpi" (dots per inch), in scanners and printers
 - 200-4800 dpi most common ranges

Raster format

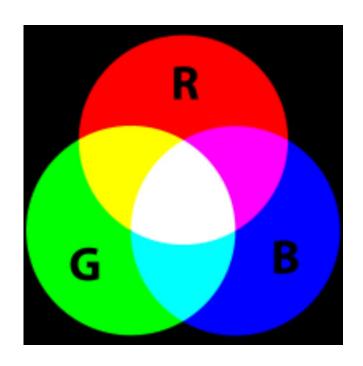

- In raster format an image (picture) is represented by a matrix of "pixels"
- The quality of a picture is determined also by the number of bits used to represent one pixel (called depth)
 - 1 bit for black and white
 - 8-16 bits for grey scale (most common ranges)
 - 12-48 bits for color images (most common ranges)
- Colors are represented by three numbers, one for each "color component"
- Big file sizes for (uncompressed color) pictures
 - For example, one color page scanned at 600 dpi is about 100 MB

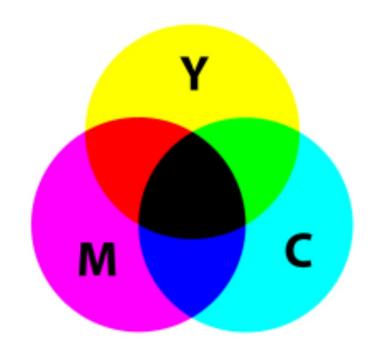

RGB and CMY color components

Additive color mixing

Subtractive color mixing

Common raster image file formats

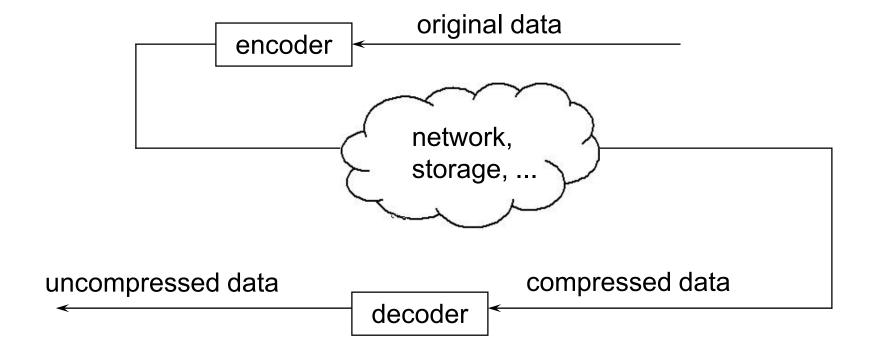

- Big file sizes for (uncompressed color) pictures.
 Compression is needed
- Lossless compression
 - G3, G4, JBIG (fax)
 - GIF, PNG (simple graphics)
- Lossy compression
 - JPEG (all kind of images)
- BMP, RAW (sensor output), DNG (Digital Negative), etc.
- Image containers
 - TIFF

Compression of information

lossless compression: the uncompressed data is identical (bit by bit) to the original data

lossy compression: the uncompressed data contains less "information" than the original data

Lossless compression techniques

- There are two main classes of lossless data compression methods
 - Symbol-wise encoding (Huffman)
 - Dictionary encoding (LZV)
- Symbolwise encoding
 - The basic idea is that the most frequent symbols can be coded with fewer bits (short codewords) than the less frequent symbols (long codewords)
 - Coders work by taking one symbol at the time from the input string, and coding it with a codeword whose length depends on the frequency (probability) of the symbol in the given alphabet
 - One of the most common symbol encoders is the Huffman coding
- Dictionary coding
 - The basic idea is to replace a sequence of symbols in the input string with an "index" in a dictionary (list) of "phrases"
 - zip, .rar, .tar, etc

Comparison of lossless compression methods

Common raster image file formats

- Lossless compression
 - G3, G4, JBIG (fax)
 - GIF, PNG (simple graphics)
- Lossy compression
 - JPEG (all kind of images)
- BMP, RAW (sensor output), DNG (Digital Negative), etc.
- Image containers
 - TIFF

Lossless compression G3, G4, JBIG

- CCITT standard (since late seventies) for fax
 - Comite' Consultatif Internationale de Telegraphie et de Telephonie, part of ITU – International Telecommunications Union
- Specifies resolution
 - 200 x 100 dpi (standard) or 200 x 200 dpi (hig resolution)
- Basically bi-level documents (black and white), even if G4 includes also provisions for optional greyscale and color images
- A one-page A4 document contains 1728x1188 pixels (bits), which is about 2 MB of data (too much to be sent over telephone lines, especially at that time)
- G3 specifies two coding (compression) methods.
 - One-dimensional (each line treated separately)
 - Two-dimensional (called READ, exploits coherence between succesive scan lines)
- G4 and JBIG are more recent versions of the standard, which allow a much better compression

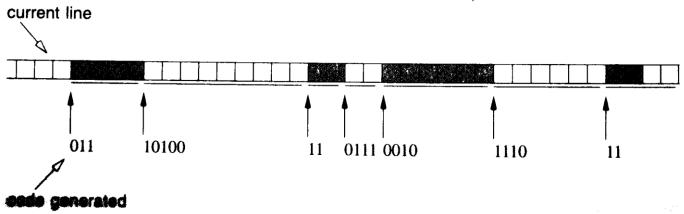

One-dimensional compression

It is basically a Huffman
-
coding, with pre-set
probabilities of the
different "run lenghts", i.e.
the number of
consecutive pixels either
black or white

code table		color	of run
	run length	white	black
	0	00110101	0000110111
	1	000111	010

	3	1000	10
	4	1011	011
	5	1100	0011
	6	1110	0010
	7	1111	00011
	8	10011	000101
	9	10100	000100
		•••	•••

Common raster image file formats

- Lossless compression
 - G3, G4, JBIG (fax)
 - GIF, PNG (simple graphics)
- Lossy compression
 - JPEG (all kind of images)
- BMP, RAW (sensor output), DNG (Digital Negative), etc.
- Image containers
 - TIFF

GIF and PNG

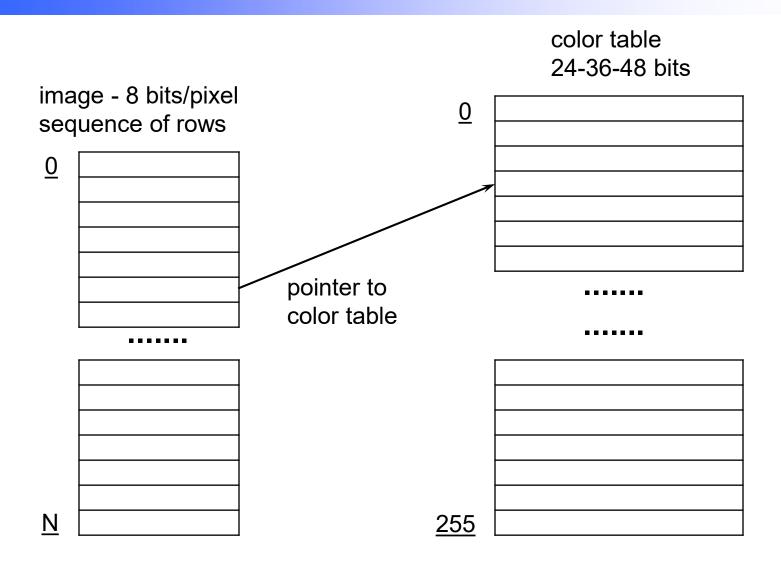

- GIF Graphics Interchage Format, is probably the most used "lossless" compression format for images (late eighties)
- Each file may contain several images (it supports animation)
- In an image, each pixel is represented by 8 bits (or less), and the value is an index in a color table, which can be included in the file (if not included, a standard color table is used)
- The color table has 256 entries, therefore a GIF image can have a "palette" of at most 256 colors (which is much less than the colors actually in the picture)
- The pixel index values are compressed using the LZW (zip) method
- The LZW coded information is divided in blocks, preceded by a header with a byte count, so it is possible to skip over images without decompressing them
- PNG (Portable Network Graphics) is essentially the same, and was defined some years later to avoid the use of the "proprietary" LZW compression algorithm
 - PNG uses "public domain" gzip or deflate methods
 - It incorporates also several improvements over GIF

Pixel representation in GIF

Common raster image file formats

- Lossless compression
 - G3, G4, JBIG
 - GIF, PNG
- Lossy compression
 - JPEG
- BMP, RAW (sensor output), DNG (Digital Negative), etc.
- Image containers
 - TIFF

JPEG

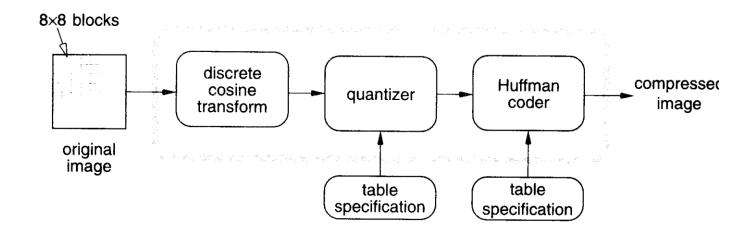

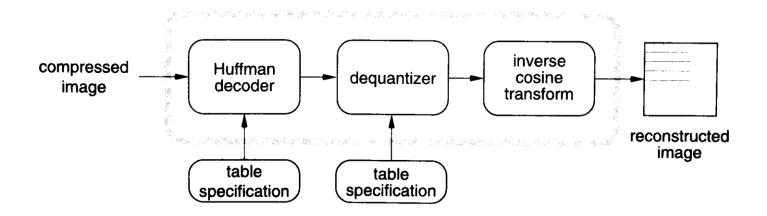

- For grayscale and color images, lossless compression still results in "too many bits"
- Lossy compression methods take advantage from the fact that the human eye is less sensitive to small greyscale or color variation in an image
- JPEG Joint Photographic Experts Group and Joint Binary Image Group, part of CCITT and ISO
- JPEG can compress down to about one bit per pixel (starting with 8-48 bits per pixel) still having excellent image quality
 - Not very good for fax-like images
 - Not very good for sharp edges and sharp changes in color
- The encoding and decoding process is done on an 8x8 block of pixels (separately for each color component)

JPEG encoding and decoding

original pixel values

Common raster image file formats

- Lossless compression
 - G3, G4, JBIG
 - GIF, PNG
- Lossy compression
 - JPEG
- BMP, RAW (sensor output), DNG (Digital Negative), etc.
- Image containers
 - TIFF

TIFF

- Tagged Image File Format file format that includes extensive facilities for descriptive metadata
 - note that TIFF tags are not the same thing as XML tags
- Owned by Adobe, but public domain (no licensing)
- Large number of options
 - Problems of backward compatibility
 - Problems of interoperability
 (Thousands of Incompatible File Formats (2))
- Can include (and describe) four types of images
 - bilevel (black and white), greyscale, palette-color, full-color
- Support of different color spaces
- Support of different compression methods
- Much used in digital libraries and archiving

Representation of information within a computer

- Numbers
- Text (characters and ideograms)
- Documents
- Images
- Video

Audio

Representing video

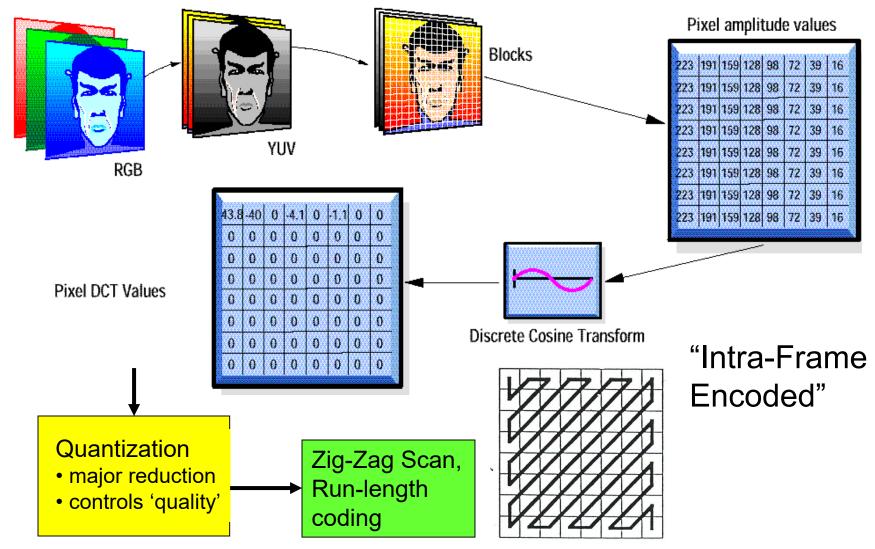

- Sequence of frames (still images) displayed with a given frequency
 - NTSC 30 f/s, PAL 25 f/s, HDTV 60 f/s
- Resolution of each frame depend on quality and video standard
 - 720x480 NTSC, 768x576 PAL, 1920x1080 HDTV, 3840×2160 UltraHD, 4096×2160 4K
- Uncompressed video requires "lots of bits"
 - e.g. 1920x1080x30x24 = ~1,5 GB/sec
- It is possible to obtain very high compression rates
 - Spatial redundancy (within each frame, JPEG-like)
 - Temporal redundancy (across frames)

Spatial Redundancy Reduction (DCT)

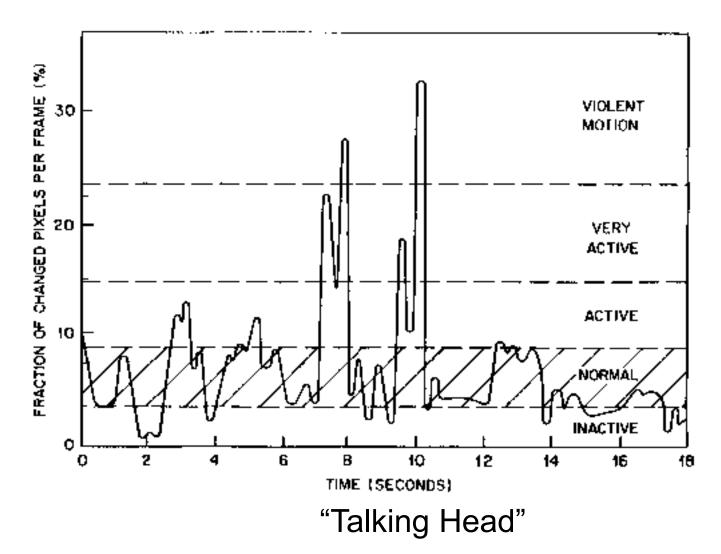

Temporal Activity

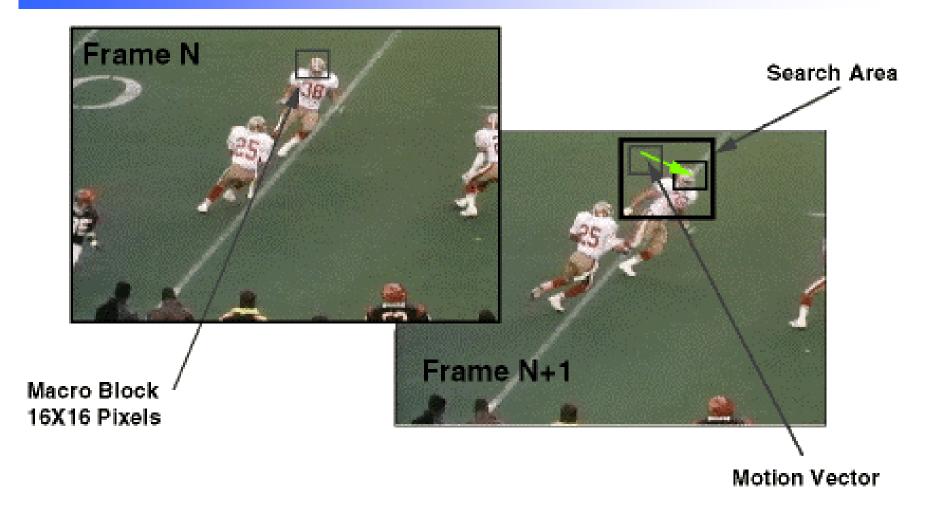

Temporal Redundancy Reduction (motion vectors)

Types of frames in compression

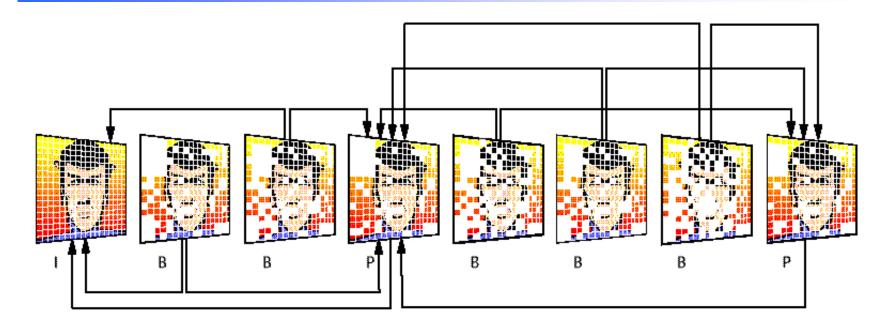

- MPEG uses three types of frames for video coding (compressing)
 - I frames: intra-frame coding
 - Coded without reference to other frames
 - Moderate compression (DCT, JPEG-like)
 - Access points for random access
 - P frames: predictive-coded frames
 - Coded with reference to previous I or P frames
 - B frames: bi-directionally predictive coded
 - Coded with reference to previous and future I and P frames
 - Highest compression rates

Temporal Redundancy Reduction

- I frames are independently encoded
- P frames are based on previous I and P frames
- B frames are based on previous and following I and P frames

SUMPE SCHOOL Typical Compression Performance abCD

Representation of information within a computer

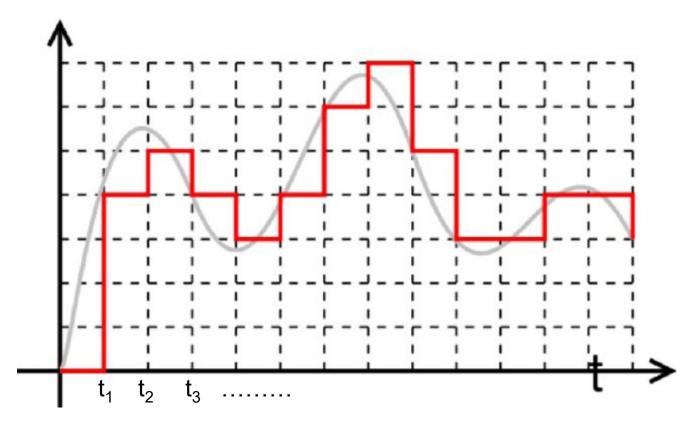

- Numbers
- Text (characters and ideograms)
- Documents
- Images
- Video
- Audio

Digitization of audio (analog) signals

The signal is sampled (the intensity is measured) at fixed time intervals and the "curve" is replaced by a sequence of numbers

Digitization of audio (analog) signals

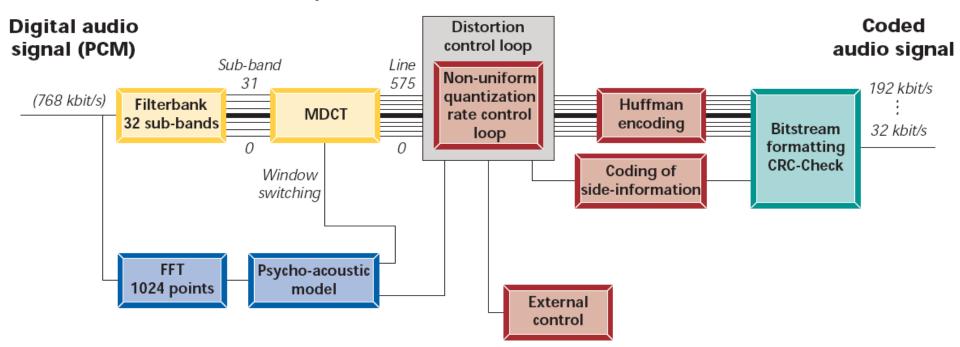

- The audio signal is a vibration that hits the human ear
- The (audio) signal can be considered as the sum of a series of sinusoidal signals, each with increasing frequency (Fourier theorem)
- The human ear can hear "vibrations" that go from 15-20 times per second (Hertz) to 20000 Hertz (20 KHz)
- Sampling rate should be at least the double of the highest frequency in the signal that we want to maintain (Shannon theorem)
- Sampling at 44 KHz will "keep" all the frequencies up to 20 KHz
- Transforming the "sequence of samples" back into an audio signal, the human ear will not detect that this signal has "lost" the higher frequencies

Representing audio

- MPEG-1 defines three different schemes (called *layers*) for compressing audio
- All layers support sampling rates of 32, 44.1 and 48 kHz
- Each sample 8-16 bits
- MP3 is MPEG-1 Layer 3

Multimedia file formats

- A muxer (abbreviation of multiplexer) is a "container" file that can contain several video and audio streams, compressed with codecs
 - Common file formats are AVI, DIVx, FLV, MKV, MOV, MP4, OGG, VOB, WMV, 3GPP
- A codec (abbreviation of coder/decoder) is a "system" (a series of algorithms) to compress video and audio streams
 - Common video codecs are HuffyYUV, FLV1, HEVC, Mpeg2, xvid4, x264, H264, H265
 - Common audio codecs are AAC, AC3, MP3, PCM, Vorbis
